

NEURAL MACHINE TRANSLATION

A DISSERTATION

SUBMITTED TO THE DEPARTMENT OF COMPUTER SCIENCE

AND THE COMMITTEE ON GRADUATE STUDIES

OF STANFORD UNIVERSITY

IN PARTIAL FULFILLMENT OF THE REQUIREMENTS

FOR THE DEGREE OF

DOCTOR OF PHILOSOPHY

Minh-Thang Luong

June 2016

1.4	<b>Neural machine translation</b> – example of a deep recurrent architecture proposed by Sutskever et al. [24] for translating a source sentence “I am a student” into a target sentence “Je suis étudiant”. Here, “_” marks the end of a sentence. . . . .	4

# Chapter 1

## Introduction

The Babel fish is small, yellow, leech-like, and probably the oddest thing in the universe. It feeds on brainwave energy ... if you stick a Babel fish in your ear, you can instantly understand anything in any form of language.

---

*The Hitchhiker's Guide to the Galaxy.* Douglas Adams.

Human languages are diverse and rich in categories with about 6000 to 7000 languages spoken worldwide.<sup>1</sup> As civilization advances, the need for seamless communication and understanding across languages becomes more and more crucial. Machine translation (MT), the task of teaching machines to learn to translate automatically across languages, as a result, is an important research area. MT has a long history [9] from the original philosophical ideas of universal languages in the seventeen century to the first practical instances of MT in the twentieth century, e.g., one proposal by Weaver [26]. Despite several excitement moments that led to hopes that MT will be solved “very soon”, e.g., the 701 translator<sup>2</sup> developed by scientists at George Town and IBM in the 1950s or a simple vector-space transformation technique<sup>3</sup> proposed by Google researchers at the beginning of the twenty-first century, MT remains to be an extremely challenging problem.<sup>4</sup> To understand why MT is difficult, let us trace through one “evolution” path of MT which crosses

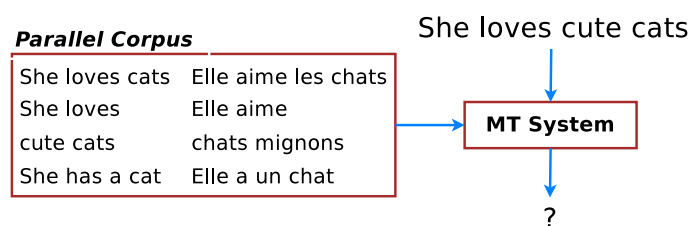

Figure 1.1: **Machine translation (MT)** – a general setup of MT. Systems build translation models from parallel corpora to translate new unseen sentences, e.g., “She loves cute cats”.

through techniques that are used extensively in commercial MT systems.

Modern statistical MT started out with a seminal work by IBM scientists [2]. The proposed technique requires minimal linguistic content and only needs a *parallel corpus*, i.e., a set of pairs of sentences that are translations of one another, to train machine learning algorithms to tackle the translation problem. Such a language-independent setup is illustrated in Figure 1.1 and remains to be the general approach for nowadays MT systems. For over twenty years since the IBM seminal paper, approaches in MT such as [3, 4, 7, 13, 14, 15, 20], are, by and large, similar according to the following two-stage process (see Figure 1.2). First, source sentences are broken into chunks which can be translated in isolation by looking up a “dictionary”, or more formally a *translation model*. Translated target words and phrases are then put together to form coherent and natural-sounding sentences by consulting a *language model* (LM) on which sequences of words, i.e., *n-grams*, are likely to go with one another.

Figure 1.2: **Phrase-based machine translation (MT)** – example of how phrase-based MT systems translate a source sentence “She loves cute cats” into a target sentence “Elle aime les chats mignons”: sentences are split into chunks and phrases are translated.

The aforementioned approach, while has been successfully deployed in many commercial systems, does not work very well and suffers from the following two major drawbacks. First, translation decisions are *locally determined* as we translate phrase-by-phrase and

long-distance dependencies are often ignored. Second, it is slightly “strange” that language models (LMs), despite being a key component in the MT pipeline, utilize context information that is both short, consisting of only a handful of previous words, and target-only, never looking at the source words. These shortcomings in LMs gives rise to a new wave of *hybrid* systems which aim to empower phrase-based MT with neural network components, most notably neural language models (NLMs).

NLMs were first proposed by Bengio et al. [1] as a way to combat the “curse” of dimensionality suffered by traditional LMs. In traditional LMs, one has to explicitly store and handle all possible  $n$ -grams occurred in a training corpus, the number of which quickly becomes enormous. As a result, existing MT systems often limit themselves to use only short, e.g., 5-gram, LMs [8], which capture little context and cannot generalize well to unseen  $n$ -grams. NLMs address these concerns by using distributed representations of words and not having to explicitly store all enumerations of words. As a result, many MT systems, [17, 21, 25], *inter alia*, start adopting NLMs alongside with traditional LMs. To make NLMs even more powerful, recent work [6, 22] propose to condition on source words beside the target context to lower uncertainty in predicting next words (see Figure 1.3).<sup>5</sup>

Figure 1.3: **Source-conditioned neural language model (NLM)** – example of a source-conditioned NLM proposed by Devlin et al. [6]. To evaluate a how likely a next word “rive” is, the model not only relies on previous target words (context) “promenade le long de la” as in traditional NLMs [1], but also utilizes source context “along the South Bank” to lower uncertainty in its prediction.

These hybrid MT systems with NLM components, while having addressed shortcomings of traditional phrase-based MT, still translate locally and fail to capture long-range

<sup>5</sup>In [6], the authors have constructed a model that conditions on 3 target words and 11 source words, effectively building a 15-gram LM.

dependencies. For example, in Figure 1.3, the source-conditioned NLM does not see the word “stroll”, or any other words outside of its fixed context windows, which can be useful in deciding that the next word should be “bank” as in “river bank” rather “financial bank”. More problematically, the entire MT pipeline is already complex with different components needed to be tuned separately, e.g., translation models, language models, reordering models, etc.; now, it becomes even worse as different neural components are incorporated. Neural Machine Translation to the rescue!

Neural Machine Translation (NMT) is a new approach to translating text from one language into another that captures long-range dependencies in sentences and generalizes better to unseen texts. The core of NMT is a single deep neural network with hundreds of millions of neurons that learn to directly map source sentences to target sentences. Despite being relatively new [5, 12, 24], NMT has already shown promising results, achieving state-of-the-art performances for several language pairs such as English-French [19], English-German [10, 18, 23], and English-Czech [11, 16]. NMT is appealing since it is conceptually simple and can be trained end-to-end. NMT translates as follows: it reads through the given source words one by one until the end, and then, starts emitting one target word at a time until a special end-of-sentence symbol is produced. We illustrate this process in Figure 1.4.

Figure 1.4: **Neural machine translation** – example of a deep recurrent architecture proposed by Sutskever et al. [24] for translating a source sentence “I am a student” into a target sentence “Je suis étudiant”. Here, “\_” marks the end of a sentence.

Such simplicity leads to several advantages. NMT requires minimal domain knowledge: it only assumes access to sequences of source and target words as training data and

learns to directly map one into another. NMT beam-search decoders that generate words from left to right can be easily implemented, unlike the highly intricate decoders in standard MT [13]. Lastly, the use of recurrent neural networks (RNNs) allow NMT to generalize well to very long word sequences while not having to explicitly store any gigantic phrase tables or language models as in the case of standard MT.

In this thesis, I will describe how I have pushed the limits of NMT, making it applicable to a wide variety of languages with state-of-the-art performance. We start off by providing background knowledge on RNN and NMT in Chapter 2. The following chapters detail my contributions. Chapter 3 discusses how the rare word problem in NMT is addressed with a mechanism to “copy” words from source to target; hence, extending the vocabulary coverage. Chapter 4 describes how the attention mechanism, a way to select local contexts in the source sentence as we translate, can be effectively used in NMT to better handle long sentences. Chapter 5 proposes a novel way of dealing with language complexity (rich morphology, neologisms, and informal spellings) by building a hybrid word and character level model which can gain from the flexibility of a character-level model while maintaining the speed and quality of the word-level model. Towards the future of NMT, I answer two questions in Chapter 6: (1) whether we can improve translation by jointly learning from a wide variety of sequence-to-sequence tasks such as parsing, image caption generation, and auto-encoders or skip-thought vectors; and (2) whether we can compress NMT for mobile devices. Chapter 7 wraps up and discusses remaining challenges in NMT research.
